now, simulate just the first few bytes falling into your memory space.

As bytes fall into your memory space, they make that coordinate corrupted.

Corrupted memory coordinates cannot be entered by you or The Historians, so you'll need to plan your route carefully. You also cannot leave the boundaries of the memory space; your only hope is to reach the exit.

Each byte position is given as an X,Y coordinate, where X is the distance

You and The Historians are currently in the top left corner of the memory

space (at 0,0) and need to reach the exit in the bottom right corner (at

70,70 in your memory space, but at 6,6 in this example). You'll need to

simulate the falling bytes to plan out where it will be safe to run; for

from the left edge of your memory space and  $\overline{Y}$  is the distance from the top

In the above example, if you were to draw the memory space after the first 12 bytes have fallen (using . for safe and # for corrupted), it would look like this:

```
like this:

...#...

...#..

...#..

...#..
```

You can take steps up, down, left, or right. After just 12 bytes have corrupted locations in your memory space, the shortest path from the top left corner to the exit would take 22 steps. Here (marked with 0) is one such path:

```
.0#00#0
.000#00
...#00#
..#00#.
.#.0#..
#.#0000

Simulate the first kilobyte (1024 bytes) falling onto your memory space.
Afterward, what is the minimum number of steps needed to reach the exit?
```

```
Your puzzle answer was 252.
```

--- Part Two ---

1,0 0,5

2,0

| . . # . . # .

.#..#..

|# . # . . . .

00.#000

edge of your memory space.

The Historians aren't as used to moving around in this pixelated universe as you are. You're afraid they're not going to be fast enough to make it to the exit before the path is completely blocked.

To determine how fast everyone needs to go, you need to determine the first byte that will cut off the path to the exit.

In the above example, after the byte at 1,1 falls, there is still a path to the exit:

```
0..#000
0##00#0
0#00#00
000#00#
###00##
.##0##
#.#0000

However, after adding the very next byte (at 6,1), there is no longer a path to the exit:
```

```
path to the exit:

...#..#
.##.##
###.##
###.##

So, in this example, the coordinates of the first byte that prevents the
```

exit from being reachable are 6,1.

Simulate more of the bytes that are about to corrupt your memory space. What are the coordinates of the first byte that will prevent the exit from being reachable from your starting position? (Provide the answer as two integers separated by a comma with no other characters.)

Your puzzle answer was 5,60.

Both parts of this puzzle are complete! They provide two gold stars: \*\*

At this point, you should return to your Advent calendar and try another puzzle.

If you still want to see it, you can get your puzzle input.
